

AI Career Operations System

A complete multi-agent operating system that runs a career transition like an operations function. Five agents, two skills, eight databases, one daily workflow.

The Problem

A career transition produces the same failure mode as any unmanaged operation: noise, inconsistency, no system of record. Hundreds of postings, mostly wrong. Resumes drift out of sync. Applications get tracked in your head until they don't. And the real risk — taking another misaligned job because evaluating each opportunity rigorously does not scale by hand.

The Approach: run the search as an operations function

Not a job scanner — a managed pipeline with specialist agents, a single source of truth, and a daily cadence.

The Differentiators

A full operating system, not a tool. Five coordinated agents, two skills, eight linked Notion databases, a daily cadence. Most people build a scraper; this operates a function.

It encodes judgment, not keywords. The scoring rubric carries hard-won personal criteria — including a hard-stop for the role type that was a bad fit last time. Its job is to protect against the wrong roles, every run.

It closes every loop. Scans, application status, resume versions, networking, and weekly metrics all live in one linked system of record. Nothing is tracked in someone's head.

Proven by its own output. This system ran the search that produced this very portfolio and the applications behind it. It is in production on the most important project its author has.
