

Autonomous Planning System

Scheduled cloud agents that plan your week and verify what you actually did — then wait for your approval.

The Problem

Planning tools make you do the planning, and almost none can answer the question that matters most at the start of a day: did the things I committed to yesterday actually happen?

The Approach

Two agents on a cron — a Friday weekly planner and a weekday daily reviewer. Each reads real context across five tools, drafts a proposal where every action is a checkbox, and waits. Only what the human approves gets created. The agent does the synthesis; the human keeps the judgment.

The Differentiator: it verifies reality, not memory

For each of yesterday's tasks the agent checks the evidence — a commit, a sent message, a file modified at a specific time — and marks it Verified Complete, Likely Complete, or Unverified. Knowing a document was edited at 4:47 PM and confirmed as yours beats relying on memory. It catches dropped commitments before they become problems. This is the feature that makes the system trustworthy.

What This Demonstrates

- **Scheduled autonomous operation** — cloud cron, runs with no machine on
- **Multi-source reconciliation** — calendar, messages, docs, notes into one plan
- **Evidence-based verification** — confirms work against artifacts, not self-report
- **Human-in-the-loop design** — proposes everything, executes only what is approved, full audit log

Total human time: 5–10 minutes a day. The agent does the synthesis; the human does the judgment.

Claude · cloud cron · calendar / messaging / docs integration · human-in-the-loop approval
